It must be cleared so that the next action potential can cause another synaptic transmission. There are NT transports on the presynaptic membrane that allows for re-uptake so enzyme can destroy them or be released back into vesicles.

The entry of Ca²⁺ causes the synaptic vesicles to fuse with the presynaptic terminal and release a chemical (neurotransmitter) into the synapse. 4. The neurotransmitters bind to proteins called receptors on the postsynaptic terminal that can directly or indirectly open ion channels resulting in EPSPs or IPSPs.

The process by which this information is communicated is called synaptic transmission and can be broken down into four steps. First, the neurotransmitter must be synthesized and stored in vesicles so that when an action potential arrives at the nerve ending, the cell is ready to pass it along to the next neuron.

This process is termed synaptic transmission. The picture above is a simple step-by-step illustration of how synaptic transmission works. To sum it up, one could think of synaptic transmission as consisting of 4 steps:

Synaptic Transmission - Explorable

Synaptic Transmission. A process called synaptic transmission is necessary for these neurons to communicate. Chemical synapses enable the transmission of information (action potentials) from one neuron to another. These synapses require chemicals known as neurotransmitters.
