Eukaryotic gene expression is regulated during transcription and RNA processing, which take place in the nucleus, and during protein translation, which takes place in the cytoplasm. Further regulation may occur through post-translational modifications of proteins.

You have tens of thousands of genes in your genome. Does that mean your cells express all of those genes, all the time? Not by a long shot! Even an organism as simple as a bacterium must carefully regulate gene expression, ensuring that the right genes are expressed at the right time. ### Regulation of gene expression - Wikipedia

In multicellular organisms, gene regulation drives cellular differentiation and morphogenesis in the embryo, leading to the creation of different cell types that possess different gene expression profiles from the same genome sequence. [MCAT biology 1 Flashcards | Quizlet](#)

Gene regulation in eukaryotes adds complexity by involving the interaction of many genes and other proteins called enhancers. Because of this, more room is required than is available near the promoter. Enhancers are short, non-coding regions of DNA found in eukaryotes. They function similarly to activators but act at a much greater distance from the promoter.

### Regulation of Transcription in Eukaryotes - The Cell ...

Regulation of Transcription in Eukaryotes Although the control of gene expression is far more complex in eukaryotes than in bacteria, the same basic principles apply. The expression of eukaryotic genes is controlled primarily at the level of initiation of transcription, although in some cases transcription may be attenuated and regulated at subsequent steps.

### Gene expression - Wikipedia

Gene expression is the process by which information from a gene is used in the synthesis of a functional gene

product. These products are often proteins, but in non-protein coding genes such as transfer RNA (tRNA) or small nuclear RNA (snRNA) genes, the product is a functional RNA.
